July 2003

Abstract

The views expressed in this Working Paper are those of the author(s) and do not necessarily represent those of the IMF or IMF policy. Working Papers describe research in progress by the author(s) and are published to elicit comments and to further debate.

Government-linked companies (GLCs) have a significant presence in Singapore's corporate sector. Unlike parastatals in many other countries, these companies are run on a competitive, commercial basis, ostensibly without government privileges. Based on data from publicly listed GLCs and non-GLCs, we indeed find no evidence that GLCs have easier access to credit. However, we do find that being a GLC is rewarded in financial markets with a positive premium, over and above what can be explained by the usual determinants of Tobin's q .

I. INTRODUCTION

As part of its post-independence industrialization plan, the Singapore government assumed a proactive entrepreneurial role by establishing state enterprises (called government-linked companies, or GLCs) in key sectors such as manufacturing, finance, trading, transportation, shipbuilding, and services. In this respect, Singapore was different from Hong Kong (whose economic growth was driven by private enterprises) and other East Asian economies like Japan, Taiwan, and South Korea (where active industrial policy did not involve widespread government ownership of enterprises). By most accounts, however, this strategy of “state capitalism” has been quite successful. GLCs have evolved into an important national institution, and the major companies have become well-recognized corporate names regionally and even—in the case of Singapore Airlines—globally.

Unlike parastatals in many countries, Singapore’s GLCs bear quite a close resemblance to private enterprises. The government clearly subscribes to what has been termed the “managerial” view in the ongoing debate on public versus private ownership, which argues that competition rather than ownership per se is the key to efficiency.² GLCs are run on a commercial basis, with a focus on bottom line performance. They have not been used for social or employment generation purposes. They compete with private firms and multinational companies and, in some cases, with each other. Many of them have been partially privatized and are listed on the local stock exchange.

Yet, while GLCs have undoubtedly been a major element in Singapore’s economic development, there has recently been an active debate concerning their future role in the economy.³ Criticism of GLCs falls into two broad categories: the first contends that GLCs tend to do better than private sector firms because their institutional relationship with the government gives them special advantages in terms of access to funds, tenders, and opportunities, with the result that they have closed large areas of the economy to the private sector and stifled entrepreneurship; the second contends that GLCs tend to do worse than private sector firms because their managers are mainly civil servants who lack business acumen, and their investments may be politically, rather than commercially, motivated.

² The alternative view, termed the “political” or “ownership” view, maintains that government-owned enterprises are intrinsically inefficient because governments pursue objectives in addition to, and in conflict with, profit maximization, and this political interference can distort the objectives and constraints faced by managers of such enterprises. See Shleifer (1998) for an example of this view, and Bardhan and Roemer (1992) for an example of the managerial view.

³ This debate was sparked by the release of a report by a government-appointed committee on the role of the government in business (Singapore Economic Review Committee, 2002); the committee’s final recommendations are summarized in Singapore Ministry of Trade and Industry (2003). An earlier debate—reflecting many of the same arguments—occurred in the late 1980s, when several public enterprises were fully or partially privatized.

The purpose of this paper is to investigate the differences between GLCs and private sector firms empirically. To our knowledge, this has not been attempted so far; the discussion has been mostly anecdotal. Using data on publicly listed GLCs and a control sample of non-GLCs, we consider two questions: (1) Do GLCs benefit from special financial advantages? and (2) Do the financial markets value GLCs and non-GLCs differently, and if so, why? We examine the first claim by comparing the investment behavior of GLCs and non-GLCs—if GLCs do indeed receive preferential financing, they would tend to be less liquidity-constrained than non-GLCs. Next, we run Tobin's q regressions to find out if government ownership/affiliation makes a difference to the market valuation of a company.

The rest of the paper is organized as follows. Section II provides some background information on the history of GLCs and their role in the economy. Section III describes the data. Section IV presents the liquidity tests. Section V presents the Tobin's q regressions. Section VI concludes.

II. BACKGROUND

To jumpstart industrialization in the late 1960s, the Singapore government created GLCs and statutory boards to spearhead development in various sectors of the economy.⁴ The stated rationale for this strategy was to compensate for the lack of private sector funds or expertise. Pioneer GLCs included the Keppel, Sembawang, and Jurong Shipyards, which spurred the development of Singapore as a major shipbuilding and ship repair center; the Development Bank of Singapore, which was set up to provide development financing; and Neptune Orient Lines, which was formed to leverage on the island's strategic location. Some GLCs were set up for strategic reasons, notably Chartered Industries and Allied Ordnance in the defense industry. Many of these early companies were joint ventures with foreign investors: for example, the Singapore Refining Company, which provided the catalyst for the growth of the oil refining industry, was a joint venture with Caltex and British Petroleum, while the Petrochemical Corporation of Singapore, which launched Singapore's entry into the petrochemicals industry, was a joint venture with Shell and a Japanese consortium.

In 1974, the government (through the ministry of finance) established a limited holding company, Temasek Holdings, to manage its investments in GLCs. At that time, 36 companies were transferred to Temasek's control.⁵ Since then, rapid economic growth has

⁴ Statutory boards are legislated under individual acts of parliament that define their functions, scope, and powers; they are formed under various ministries and are accountable to them through parliament. GLCs are incorporated under the Companies Act, and do not come under the direct purview of parliament. Both GLCs and statutory boards can form their own subsidiaries and associated companies.

⁵ Two other holding companies were set up around the same time: MND Holdings (owned by the ministry of national development) and Sheng-Li Holdings (owned by the ministry of defence). MND Holdings was subsequently taken over by the ministry of finance and the bulk of its GLCs transferred to Temasek. Sheng-Li Holdings (now Singapore Technologies) is responsible for defense-related GLCs.

afforded GLCs the scope and opportunities to expand and diversify their operations. The 1980s and 1990s also saw the corporatization of a number of statutory boards into GLCs.⁶ Today, the total number of GLCs is estimated to be in the hundreds. Temasek Holdings directly holds 22 first-tier GLCs, all of which have subsidiaries or associate companies, which in turn, often have third-tier subsidiaries, and so on. The companies are involved in a wide range of areas, including finance, telecommunications, transport and logistics, property, infrastructure and engineering, and utilities.

Temasek Holdings and its subsidiaries are registered companies under the Companies Act, subject to all the same requirements as private businesses. Many of its companies are listed on the Singapore Exchange; according to Temasek, the major listed companies account for over 20 percent of the total market capitalization.⁷

In addition to GLCs held directly or indirectly by Temasek Holdings, there are also a number of enterprises that are fully or majority owned by statutory boards. Such enterprises may also be classified as GLCs, to the extent that their shares are owned ultimately by the government. A prime example is the Comfort Group, a publicly listed land transportation services conglomerate owned primarily by the Singapore Labor Foundation (a statutory board).

According to the government, GLCs operate fully as for-profit commercial entities, on the same basis as private sector companies: they are expected to provide commercial returns, commensurate with risks taken; they are subject to the the same regulations and market forces as private entrepreneurs; and they do not receive any subsidies or preferential treatment from the government. In an early survey of public enterprises in Singapore, Lee (1976, p.57) concludes that “[g]overnment control is in fact very loose” and that the government “normally does not interfere with the management of the companies directly.” Lee (1976, p.58) further notes that GLCs appear to receive few, if any, special privileges by virtue of their government ownership:

Tax holidays and tax concessions are applied generally to all companies as long as they fulfill the conditions of pioneer status and export orientation. Most of the public enterprises obtain credit from the Development Bank of Singapore, but the interest rate is usually not lower than that of other banks.... A few government companies may secure orders of goods and services from government departments. A few said they might squeeze a lower price from suppliers of input of materials because they were

⁶ For example, the Telecommunications Authority of Singapore was converted to Singapore Telecommunications in 1992, the Public Utilities Board’s electricity sector functions were spun off to create Singapore Power in 1995, and the Port Authority of Singapore was converted into PSA Corporation in 1997.

⁷ The listed first-tier companies are: DBS Bank, Keppel Corporation, Neptune Orient Lines, SembCorp Industries, Singapore Airlines, SMRT Corporation, and Singapore Telecommunications. See <http://www.temasekholdings.com.sg/>.

government-owned.... To the question, 'whether they can obtain prior information regarding the government's future policy measures', practically all of them replied negatively.

The main advantage of government ownership appears to be the positive signal it sends to the markets. The following statement by a GLC manager, cited in Low (1991, p.65), sums it up succinctly: "Being linked to Government is of course useful. It gives the company credibility and nobody will think you are a fly-by-night operation. But the company has to justify itself and earn its keep by marketing right products at the right time as no favors are given or expected."

Indeed, many GLCs have consistently posted a strong financial performance. But the rapid growth of GLCs—both in size and in number—has led to concerns that they are encroaching into too many industries, effectively crowding out the private sector and hindering the development of a critical mass of thriving local enterprises. Among small- and medium-sized private enterprises in particular, GLCs are still perceived to have unfair advantages in terms of access to funds, tenders, and opportunities. Other critics argue that GLCs are less efficient than private sector firms, due to their institutional relationship with the government, the market structure in which they operate, or the management systems applied within them. For example, GLC managers are usually appointed from the ranks of senior civil servants and military officers, and while they are generally of a high quality and are promoted on the basis of their performance—the Singaporean civil service being "an extreme example of a meritocracy" (Krause, 1987, p.119)—they have also been criticized for being too risk-averse and lacking sufficient entrepreneurial drive.⁸ There have also been charges that certain GLC investments have been politically rather than commercially motivated. And being linked to the government may sometimes be a hindrance rather than an advantage; in recent years, some countries have been reluctant to allow Singaporean GLCs to invest in sectors considered nationally strategic.⁹

III. DATA AND DESCRIPTIVE STATISTICS

There is very little publicly available information on GLCs in Singapore. Temasek Holdings lists its major companies on its website, but not all its (numerous) subsidiaries and associated companies. In fact, the definition of a GLC has itself been the source of some controversy. Singapore's Department of Statistics defines GLCs as companies in which the

⁸ In recent years, some of the large GLCs saw management shake-ups, with new senior executives brought in from the private sector, some from abroad. A number of these foreign executives subsequently left before completing their contracts. The government has put this down to coincidence, maintaining that it does not play a direct role in recruitment decisions made by the GLCs' boards.

⁹ In 1999–2000, Singapore Telecommunications was defeated in takeover attempts in Hong Kong, SAR and Malaysia, largely for this reason.

government's effective ownership of voting shares is 20 percent or more.¹⁰ However, as argued in United States, State Department (2001), this definition excludes many second or third-tier GLC subsidiaries—for example, if Temasek owns 50 percent of a first-tier GLC, and that GLC owns 30 percent of a subsidiary, the effective government ownership of the subsidiary is calculated to be only 15 percent and as a result, the subsidiary is not considered to be a GLC. It can be argued that companies where the government's formal shareholding is less than 20 percent should still be considered government-linked, even if they are not effectively government-owned. For example, if the other shareholders individually own a miniscule fraction of the company, a mere 5 percent government ownership can entail de facto control of the company. Thus, the government may be the largest shareholder (and therefore have a controlling stake) with an ownership fraction of less than 20 percent if the other shareholders are atomistic.

For the purposes of this paper, we classify a firm as a GLC if one of its *substantial shareholders* is Temasek Holdings or a statutory board. (Under the Companies Act, an individual is considered to have substantial shareholding in a company if he or she has an interest in 5 percent or more of the voting shares of that company.) Firm data, including information on shareholders, were obtained from the *Corporate Handbook*, supplemented, where necessary, by information from the Singapore Exchange's website. A list of GLCs and the control group of private enterprises is presented in Table 1. We focus only on three sectors—manufacturing; transport, storage, and communications (TSC); and multi-industry—as these are areas in which GLCs have a significant presence.¹¹ We were able to obtain adequate data for the period 1994–98 for a sample of 17 GLCs and 92 private enterprises in these three sectors.

Table 2 presents summary statistics for the sample. The figures presented for each group (GLC and non-GLC) are means, medians, and standard deviations, calculated for all firms and all years. Note that the average GLC is almost ten times as large as the average non-GLC in terms of capital stock (fixed assets). Aside from this, the two groups of firms have a roughly similar set of characteristics. During the sample period, GLCs reported slightly lower average cash flow and gross sales (proportional to capital stock) compared with non-GLCs; average investment and liquid assets (also proportional to capital stock) were almost identical for the two groups. The medians of these variables are always smaller than the means, indicating that their distributions are skewed by some large values; this is true for both GLCs and non-GLCs.

Table 2 also presents the value of q , a proxy for Tobin's q (the market value of the firm relative to its replacement cost). Here, q is approximated by the market value of common

¹⁰ See Singapore Department of Statistics (2001). The list of GLCs according to this definition was not published.

¹¹ GLCs are also strongly represented in the financial and property sector but the characteristics of firms in these sectors do not lend themselves well to our empirical framework.

equity stock plus the book value of debt and preferred stock, divided by the book value of total assets. During the sample period, the average Tobin's q for GLCs exceeded the average q for non-GLCs by about 10 percent, although the median q values were comparable for the two groups. We investigate differences in Tobin's q further in Section V.

Finally, Table 2 shows the profitability of the two sets of companies, as measured by the return on total assets (ROA), which is the ratio of pretax net profits plus interest payments to total assets (both equity and nonequity capital). GLCs appear to be more profitable on average by this indicator than non-GLCs. However, the standard deviations are so large that the difference between the two means is not statistically significant at standard levels.¹² This can be verified by looking at the medians, which are much more comparable between the two groups. Furthermore, this accounting ratio has well-known weaknesses—for example, it reflects only past profitability, is not adjusted for risk, and tends to be subject to manipulation. We discuss this further in Section V.

IV. ARE GLCs LESS LIQUIDITY-CONSTRAINED?

A recurring charge against GLCs is that they enjoy financial privileges and do not compete on an equal footing with private enterprises. Krause (1987, p.119), for example, asserts that GLCs have a “natural advantage ... in marshalling financial resources,” since “the government saves more than it invests, and thus always has easy access to finance.” Charges of cheap funding for GLCs were also made more recently by two members of parliament during a parliamentary debate last year.¹³

One way to test if GLCs have indeed received financial advantages is to compare their investment behavior with that of their private sector counterparts. According to the imperfect capital markets literature, asymmetric information and moral hazard problems increase the cost of raising external funds for long term investment spending. Firms that have difficulty raising capital externally would tend to rely more on internal funds to finance their investment spending. Thus, their investment spending would tend to be strongly correlated with their liquidity—all else constant, more liquid firms can afford to invest more. If GLCs have preferential access to financing, this means they have an easier time raising external funds compared with their private sector counterparts. If this is the case, liquidity should be irrelevant (or at least less important) as a determinant of GLCs' investment spending. The test, therefore, involves comparing the differences in the effects of various determinants of investment spending by GLCs and private sector companies: if GLCs have better access to credit, then their investment spending should be less sensitive to a liquidity measure like cash flow than would be the case for their private sector counterparts.

¹² The t-statistic for the difference in means is 0.99 for the ROA.

¹³ See Singapore Ministry of Information (2002).

The idea for this test is not new. Previous empirical studies have determined—under a variety of settings—that firms that would appear to face the greatest problems raising capital externally tend to cut investment most in response to cash flow shortfalls. For example, Fazzari, Hubbard, and Petersen (1988) use data from American manufacturing firms, identifying firms that retain a smaller fraction of their earnings as being less liquidity constrained; Hoshi, Kashyap, and Scharfstein (1991) use data from Japanese manufacturing firms, identifying firms linked to a *keiretsu* as being less liquidity constrained; and Ramírez (1995) uses data from American companies in the 1910s, identifying firms affiliated with J.P. Morgan as being less liquidity constrained.¹⁴ Closer to our subject, Harrison and McMillan (2001) use data from Cote d'Ivoire to test if foreign firms and state enterprises are less credit constrained than domestic private firms.

The regression specification is based on that used in Hoshi, Kashyap, and Scharfstein (1991). Gross investment (normalized by the stock of capital at the beginning of the period) is regressed on liquidity measures, as well as q and gross sales. The motivation for this regression is set out in Hoshi, Kashyap, and Scharfstein (1991); we briefly review the general idea behind it below.

The regression specification takes the following form:

$$\begin{aligned} \frac{I_t}{K_{t-1}} = & \beta_0 + \beta_1 \left(\frac{CASH_t}{K_{t-1}} \right) + \beta_2 \left(\frac{LIQ_{t-1}}{K_{t-1}} \right) + \beta_3 q_{t-1} + \beta_4 \left(\frac{SALES_{t-1}}{K_{t-1}} \right) + \gamma_1 \left(GLC \times \frac{CASH_t}{K_{t-1}} \right) \\ & + \gamma_2 \left(GLC \times \frac{LIQ_{t-1}}{K_{t-1}} \right) + \gamma_3 (GLC \times q_{t-1}) + \gamma_4 \left(GLC \times \frac{SALES_{t-1}}{K_{t-1}} \right) + \varepsilon_t \end{aligned} \quad (1)$$

The dependent variable is investment during period t (I_t) as a proportion of capital stock at the beginning of period t (K_{t-1}). The independent variables are: cash flow during period t ($CASH_t$) relative to capital stock; the stock of liquid assets at the beginning of period t (LIQ_{t-1}) relative to capital stock; average Tobin's q at the beginning of period t (q_{t-1}); lagged

¹⁴ Kaplan and Zingales (1997) dispute the claim that capital market imperfections are correlated with investment–cash flow sensitivities. Their results, however, are subject to many criticisms on both conceptual and empirical grounds. For example, their conclusions are based on a very small sample of firms, which they then subdivide into five categories according to clearly endogenous variables such as the degree of liquidity. See Fazzari, Hubbard, and Petersen (2000) for a critical reply. See also Hennessy and Levy (2002) for a more recent overview of this issue.

gross sales ($SALES_{t-1}$) relative to capital stock; and the same four variables interacted with a dummy (GLC) which takes the value of 1 for GLCs and 0 otherwise.¹⁵

Neoclassical investment theory predicts that a firm's investment spending should depend positively on its investment opportunities (which we proxy with Tobin's q , q_{t-1}). The empirical investment literature finds that investment spending is also positively correlated with lagged output (which we proxy with lagged gross sales, $SALES_{t-1}$) via the accelerator effect. In the absence of friction, these two variables should be sufficient for explaining investment spending behavior. The imperfect capital markets theory extends these conventional models of investment to incorporate a role for financing constraints in determining investment. Models of asymmetric information and incentive problems in capital markets imply that information costs and the internal resources of a firm influence the shadow cost of external funds for fixed investment, holding constant underlying investment opportunities.¹⁶ Simply put, the theory predicts that, all else being equal, investment should be significantly correlated with the change in net worth (internal funds) for firms that are likely to face information-related capital market imperfections. The standard proxy for liquidity is cash flow ($CASH_t$), i.e., income after tax plus (accounting) depreciation less dividend payments.¹⁷ Following Hoshi, Kashyap, and Scharfstein (1991), we also include a stock measure of liquidity, i.e., the firm's stock of cash and short term assets such as marketable securities at the beginning of the period (LIQ_{t-1})—these are assets that be readily converted to cash to finance investment spending.

One potential concern with the regression specification is that the cash flow variable could be proxying for other factors, such as expected future profitability or higher sales. However, the inclusion of Tobin's q and gross sales as regressors should control for these factors. Another potential problem is the (mis)measurement of q . However, the point of our regression is to compare the cash flow and liquid assets coefficients for the two sets of firms. This difference should be unbiased as long as the mismeasurement is the same for both sets.

Equation (1) is estimated using ordinary least squares with fixed effects (firm and year dummies were included in each regression). The regression results, shown in Table 3

¹⁵ An alternative approach would be to estimate the investment regressions separately for GLCs and non-GLCs. However, we prefer the specification in Equation (1) since we are interested in the difference in investment behavior between GLCs and non-GLCs rather than the determinants of investment spending for each group of firms per se.

¹⁶ See Hubbard (1998), for a review of this literature.

¹⁷ As discussed in Hubbard (1998), cash flow is an imperfect proxy for the change in net worth. For example, the determination of a firm's cash flow may reflect accounting decisions (timing and financial) that muddy its correlation with the change in net worth. However, in many cases, it is the best available proxy.

column (1), indicate that the liquidity variables—cash flow and the stock of liquid assets—are indeed important explanatory variables. The other explanatory variables also have the right signs and are statistically significant.

Since our focus is on the difference between GLCs and non-GLCs, we are interested in the coefficients on the interaction terms involving the liquidity variables—if GLCs are less liquidity-constrained than non-GLCs in their investment decisions, then the coefficient on $GLC \times (CASH_t / K_{t-1})$ and $GLC \times (LIQ_{t-1} / K_{t-1})$ should be negative and significant. Table 3 column (1) shows that the GLC cash flow coefficient is smaller than the non-GLC cash flow coefficient—as evidenced by the negative coefficient on the interaction term, $GLC \times (CASH_t / K_{t-1})$ —but the difference between the two cash flow coefficients is not significant. The GLC liquid assets coefficient is larger than the non-GLC cash flow coefficient—as evidenced by the positive coefficient on the interaction term, $GLC \times (LIQ_{t-1} / K_{t-1})$ —but again, the difference between the two coefficients is not significant. Hence, our tests show no statistical difference between the GLC and non-GLC liquidity coefficients. This indicates that the GLCs in our sample are no more or less liquidity constrained in their investment decisions than their private sector counterparts. Our results are therefore consistent with the government's claim that GLCs do not enjoy cheap funding because of their link to the government.

The fact that we fail to find significant coefficients on the two interaction terms of interest may be due to the disparity in sample sizes (17 GLCs versus 92 non-GLCs), or more specifically, to the relatively small number of GLCs in our sample. Unfortunately, these 103 firms represent the limit of the data provided in the comprehensive *Corporate Handbook*. Breaking up or otherwise manipulating the samples does not change our results. To illustrate, columns (2), (3), and (4) in Table 3 present the results of same regression run separately by sector and excluding the smallest non-GLCs with average fixed assets below S\$50,000. The estimated coefficients on $GLC \times (CASH_t / K_{t-1})$ and $GLC \times (LIQ_{t-1} / K_{t-1})$ are not significantly different from zero in each case.

Our findings are, of course, based only on the sample period 1994–98. However, while relatively short, this period is actually an important one as it includes the years just after the onset of the Asian crisis. One can conjecture that if GLCs are eligible for special treatment, they will be more likely to need such favors when times are bad (e.g., during the Asian crisis) than when times are good. The fact that we find no difference in liquidity constraints between GLCs and non-GLCs during this period is thus a strong rejection of the hypothesis that GLCs have easier access to credit.¹⁸ A second, more important, caveat is that our findings obviously

¹⁸ A possible extension would involve lengthening the time frame of the analysis so as to compare results during the pre-Asian crisis period with the post-Asian crisis period. The drawback here is that the gain in length of the dataset would be offset by a loss in breadth as several companies (including some GLCs) do not have a very long history of being listed on the stock exchange.

relate only to GLCs that have been partially privatized and are publicly listed—unlisted GLCs or wholly owned government companies may well behave differently.

V. DOES THE MARKET VALUE GLCS AND NON-GLCS DIFFERENTLY?

If GLCs do not seem to be benefiting from special financial privileges, does being part of Singapore, Inc. make any difference at all? As mentioned earlier, some GLCs claim that their only advantage is that being linked to the government sends a positive signal to the markets (much like bearing a “Good Housekeeping stamp of approval”). In this section, we investigate whether the market’s valuation of a firm is correlated with its government link—if GLCs differ from non-GLCs because the government link enhances performance, for example, then one would expect GLCs to be valued more than comparable non-GLCs.

Following the approach of Lang and Stulz (1994), we focus on Tobin’s q rather than on stock market or accounting measures of performance in order to avoid some of the problems associated with those comparisons. The numerator of q —the firm’s market value—reflects the firm’s expected future profits, while the accounting rate of return measures only past profits. Furthermore, the firm’s market value also incorporates the variance of expected profits, so q includes an automatic adjustment for risk; by contrast, comparisons of stock returns have to account for differences in risk. Of course, the underlying assumptions behind the use of Tobin’s q are that financial markets are efficient and that a firm’s market value is an unbiased estimate of the present value of its cash flows.

Table 4 reports semilog regressions of q on the GLC dummy and several control variables. Theory does not dictate a specific functional form for a q equation, although Hirsch and Seaks (1993) provide evidence that the semilog form is superior. The semilog specification also has the advantage of dampening the influence of extreme or mismeasured values of q .

The first column of Table 4 shows that, controlling only for year effects, $\ln(q)$ for GLCs is higher than that for non-GLCs by 0.085 on average. This effect is significant at the 10 percent level. This is more or less in line with our earlier observation, based on a comparison of means in Table 2. How do we explain this difference in the market valuation of GLCs compared to non-GLCs?

One possible explanation is that GLCs could be concentrated in industries with better growth opportunities. Column (2) accounts for industry effects by including 14 industry dummies into the regression (the base category being “multi-industry”). However, we find that industry effects actually increase the magnitude of the GLC premium, from 8.5 percent to about 22.5 percent, and the coefficient on the GLC dummy is now significant at the 5 percent level.

Another possible explanation is that GLCs are more likely to operate in protected markets and have a certain degree of monopoly power. If GLC stocks were selling for higher prices on the Singapore Exchange because these companies were exploiting monopoly power, we would expect GLCs to have a high earnings-price ratio—earnings in the present would be

high, but market value (price) would not rise in proportion because investors would look forward to the long-run erosion of monopoly power in the face of new entry—and that inclusion of the earnings-price ratio would reduce the GLC coefficient. However, this does not appear to be the case—the third column shows that the GLC coefficient is not affected by the inclusion in the regression of the companies' earnings-price ratio.

Could the GLC premium could be reflecting a size effect and economies of scale? As noted earlier, GLCs tend to be big companies: the average GLC in our sample is about ten times larger than the average non-GLC, in terms of total assets. Larger firms may be better able to exploit scale and scope economies. If this is the case, larger firms would have a cost advantage over smaller ones, and may therefore be more profitable. Column (4) considers the effect of size (measured by the log of total assets) on q .¹⁹ If the GLC premium is due to their larger size, the inclusion of this variable should eliminate (or at least substantially reduce) the impact of the GLC dummy.²⁰ We find that the GLC dummy does decrease by about 4 percent (from 0.224 to 0.215), but remains statistically significant.

A fourth possibility is that GLCs may have lower debt-equity ratios than non-GLCs. If GLCs are less leveraged than their private sector counterparts, their probability of insolvency and failure would also tend to be lower and this may explain their higher q . Column (5) adds the debt-equity ratio to the list of regressors in order to control for the risk of bankruptcy. The results indicate this variable carries little explanatory power. More importantly, the coefficient on the GLC dummy is not materially affected by its inclusion—it remains large and statistically significant.

Or perhaps GLCs are more profitable than non-GLCs? This could be the case if they are better run, or if they receive special discounts on inputs, for example. Column (6) shows the effect of adding the return on assets (ROA) to the regression. The estimated GLC coefficient declines in size by about 8 percent (from 0.217 to 0.199), but remains statistically significant. This suggests that part of Singapore, Inc.'s added value comes from making the GLCs more profitable. However, the fact that over 90 percent of the premium survives the inclusion of this variable suggests that investors are also valuing the capitalized worth of future higher earnings from being affiliated with the government.

In summary, comparing the Tobin's q of GLCs and non-GLCs, we find evidence that the capital markets value GLCs more highly than non-GLCs. This positive and significant relation between the government link and q is robust to the inclusion of other variables that might affect firm value and thereby q , such as industry effects, size and monopoly power,

¹⁹ We use the log of assets as our measure of size in order to control for possible non-linearities (for example, the effect of size on q may diminish as size increases).

²⁰ One may also posit, a priori, a negative correlation between size and q —young, typically small, and promising firms tend to have an expected high future growth profile, so q may tend to be higher for smaller firms. In any case, the important point is that the GLC dummy remains relatively large and significant after accounting for size.

profitability, and bankruptcy risk. Taking these variables into consideration still leaves us with a GLC premium of about 20 percent.

Thus, performance measures aside, the capital markets seem to reward substantially the very fact that a company is linked to the government. This positive market perception is hard to pin down. It could simply reflect a form of brand recognition (much like how consumers are willing to pay more for goods bearing a well-known label than for similar or even identical goods without such a label). Or investors may believe—rightly or wrongly—that GLCs are backed by the government which will not let them fail in times of trouble. (Krause (1987) notes that a few small GLCs were permitted to fail in the 1970s and a few others were wound up in the 1980s, but the total capitalization of these failures was relatively small.)

VI. CONCLUSION

Singapore's GLCs are an unusual breed of state enterprises. Primarily established to catalyze the industrialization process, they have expanded into all areas of the economy, including those served by private enterprises. The government claims that GLCs are run on commercial rather than ideological grounds, with no state interference or favors: they are expected to be efficient and profitable; they are not supposed to receive special privileges or concealed subsidies; they are free to recruit staff in the open market, both at home and abroad, on competitive terms; and they should be allowed to fail if they lose money. Yet time and again, there surface charges of favoritism for GLCs at the expense of private enterprises.

Do GLCs receive special financing privileges or not? This paper finds no basis for the lingering public suspicion that GLCs have easier access to credit. Our regression results indicate that GLCs are no more or less liquidity constrained in their investment decisions than their private sector counterparts. This suggests that GLCs are competing on a level playing field as far as access to financing is concerned.

However, we do find that being a GLC is rewarded in financial markets with a premium of about 20 percent. This is after accounting for the fact that GLCs tend to be large (so that they may be able to exercise monopoly power, or exploit economies of scale and scope), profitable, and less likely to go bankrupt. This GLC premium has to reflect the market's perception of the benefits—whether real or illusory—of being linked to the government.

While our results are interesting, they certainly do not imply that the government should keep creating new GLCs or expanding existing ones. If the GLC premium is largely due to the market's perception of the benefits of being linked to the government, further proliferation of GLCs—which will tend to stretch the resources of the government—will only dilute these perceived benefits and, thereby, the premium.
